

Salton Sea Ecosystem
Restoration Plan
Inflows/Modeling Working
Group

June 13, 2005
Ontario, CA

Agenda

- ◆ **Recap of last meeting and May 18 Advisory Committee Meeting**
- ◆ **Finalize QSA Inflows**
- ◆ **Refinement of historical hydrology**
- ◆ **Projected hydrology for No Action**
- ◆ **Proposed approach to variability**
- ◆ **Approach to model development**
- ◆ **Assignments for next meeting**
- ◆ **Upcoming workgroup meeting schedule**

Recap of Previous Meeting

- ◆ Reviewed existing data and models
- ◆ Reviewed water budgets for Historic conditions, Baseline for the QSA and QSA
- ◆ Discussed approach to No Action
 - ⌘ Inflows from Mexico
 - ⌘ Local watershed contributions
 - ⌘ Evaporation
- ◆ Introduction to modeling issues
- ◆ Action items

Finalize QSA Flows

- ◆ Based on model runs presented in QSA and IID EIR/EIS Addendum
- ◆ See Table 3 of Handout

Refinements to Historical Hydrology

- ◆ **San Felipe Creek and Salt Creek**
- ◆ **Other local watershed runoff**
- ◆ **Local groundwater inflows**
- ◆ **Evaporation**

San Felipe Creek Flows

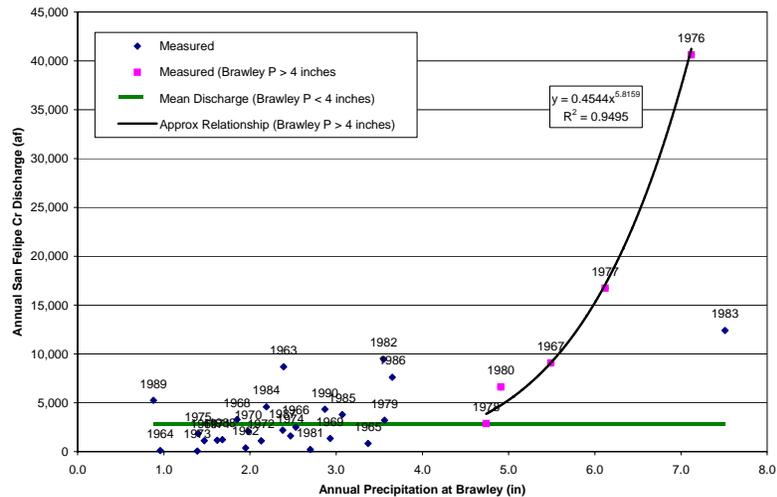

* For discussion purposes only; results are preliminary

- ◆ **San Felipe Creek flows were measured (USGS No. 10255885) from Dec 1960 – Sep 1991**
- ◆ **Record extension through approximate relationship with high precipitation**
- ◆ **Low precipitation years discharge assumed to be represented by the average of similar years in the 1960-91 period**
- ◆ **Average annual discharge for 1950-1999 estimated to be 4,634 af**

San Felipe Creek Flows

* For discussion purposes only; results are preliminary

San Felipe Creek Discharge and Watershed Precipitation

Salt Creek Flows

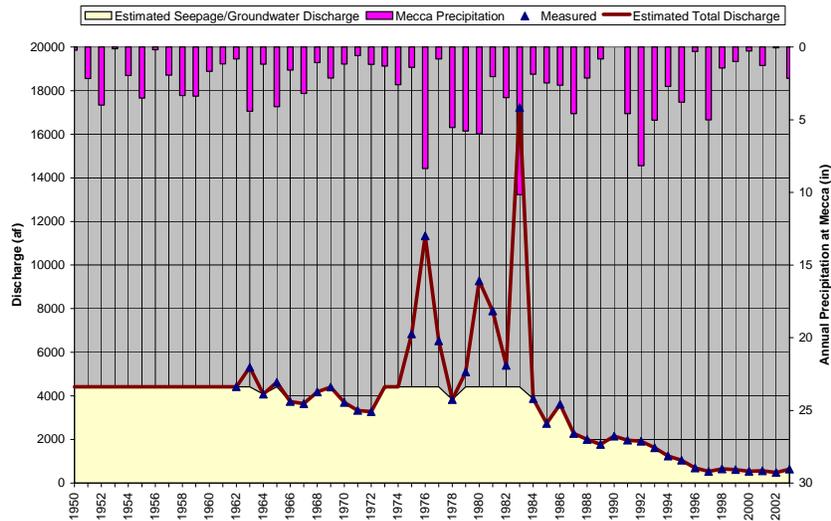

* For discussion purposes only; results are preliminary

- ◆ Salt Creek flows were measured (USGS No. 10254050) for Feb 1961 – Sep 1973 and Oct 1974 – present; some missing data in the early 1990s
- ◆ Separation of seepage/groundwater discharge baseflow from runoff needed
- ◆ Seepage/groundwater discharge pre-1961 assumed to be constant at 1961 levels
- ◆ Runoff from precipitation does not appear to materialize except in very high rainfall years
- ◆ Relationship developed relating runoff to Mecca precipitation, but not needed to fill in historic period (1950-60 was dry period)
- ◆ Average annual discharge for 1950-1999 estimated to be 4,174 af

Salt Creek Flows

* For discussion purposes only; results are preliminary

Salt Creek Annual Discharge (USGS No. 10254050)

Other Local Surface Water and Groundwater Flows

* For discussion purposes only; results are preliminary

- ◆ Remainder of local watershed discharge is ungaged
- ◆ Runoff from East shore assumed proportional to runoff from Salt Creek on a watershed area basis
- ◆ Runoff from West shore assumed proportional to runoff from San Felipe Creek on a partial watershed area basis
- ◆ Average annual runoff for 1950-1999 estimated to be 2,089 af
- ◆ Groundwater inflow (primarily from the west shore) assumed constant at 10,000 af/yr (Loeltz et al, 1975)

* For discussion purposes only; results are preliminary

Historical Inflow Summary

* For discussion purposes only; results are preliminary

◆ **Table**

Evaporation and Precipitation

- ◆ **Average annual evaporation estimated by Hely et al (1966) to be approximately 69 inches**
- ◆ **Determined by water budget, energy budget, and mass transfer techniques ... compared to sunken pan rates**
- ◆ **Water budget approach the most practical for historical analysis**
- ◆ **Net evaporation can be calibrated from the water budget**

Net Evaporation

- ◆ **Average annual precipitation for 1950-99 period is 2.7 inches (avg of Brawley and Mecca stations)**
- ◆ **Reasonable net evaporation would be approximately 66.3 inches per year**
- ◆ **Water budget calibration for 1950-1999 with estimated inflows results in average net evaporation of 66.1 inches per year**
- ◆ **No “unmeasured” terms are necessary**

* For discussion purposes only; results are preliminary

Projected Hydrology for No Action

- ◆ **Goals**
- ◆ **Limitations to “No Action” considerations**
- ◆ **Period of analysis**
- ◆ **Two step process**
 - ⌘ **develop projected hydrology using existing conditions**
 - ⌘ **adjust projected historical hydrology for “reasonably foreseeable” future actions**
- ◆ **Projected hydrology using existing conditions**
- ◆ **Adjustments to projected existing conditions hydrology**
- ◆ **Current state of hydrology for No Action**
- ◆ **Items remaining to be complete**

Projected Hydrology under Existing Conditions

- ◆ **Projected hydrology to span 2003-2077 period**
- ◆ **Where possible, climate data of 1925-1999 should be used for consistency with IID**
- ◆ **Historical refinements carried forward**

Contributions to Inflow by IID and CVWD

- ◆ **IID projected inflows based on model simulations using 1925-99 climate conditions and 1987-99 cropping patterns**
- ◆ **Estimated flows from IID to the Alamo River, New River, and to drains directly to the Sea**
- ◆ **CVWD provided projected inflows based on Coachella Valley Groundwater Management Plan simulations**

Contributions to Inflow from Local Watershed

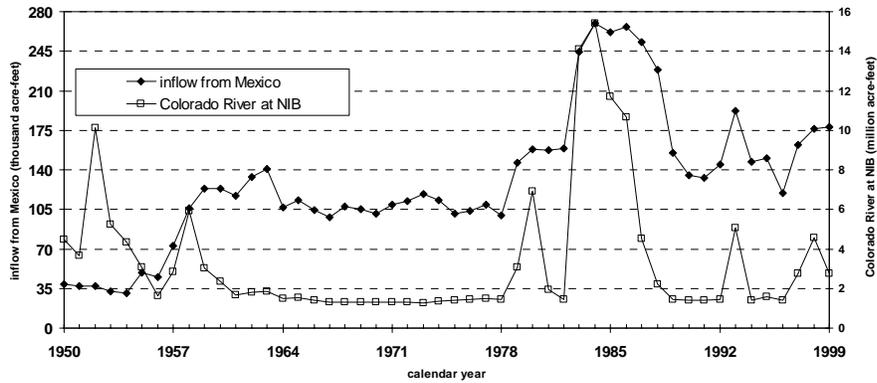

- ◆ **Salt Creek flows**
 - ⌘ assume seepage mitigation from Coachella Canal will maintain 623 af/yr
 - ⌘ precipitation runoff related to Mecca rainfall (extended for 1925-99)
- ◆ **San Felipe Creek flows developed using same approach as historic**
 - ⌘ extend record using Brawley rainfall records (extended for 1925-99)
- ◆ **Ungaged watershed inflow developed using same approach as historic**
 - ⌘ assumed proportional to Salt and San Felipe Creek runoff
- ◆ **Groundwater inflow assumed constant at 10,000 af/yr**

Mexico Inflows

- ◆ **Inflows to the New and Alamo Rivers from Mexico indicate a correlation to flows into Mexico at the NIB (Colorado and Gila River contributions)**
- ◆ **Assuming Mexico drainage patterns/water use is similar to the recent past, then Mexico inflows can be approximated from a projected flow at the NIB**
- ◆ **Projection of future flows at the NIB?**

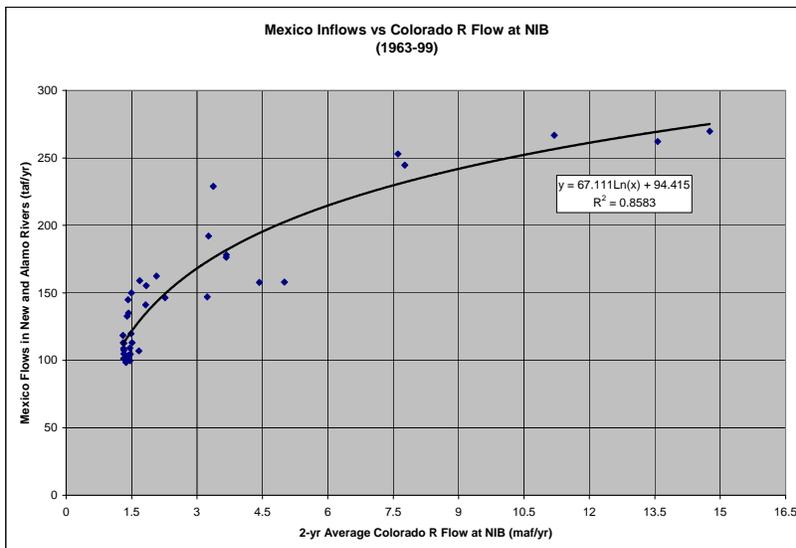

Mexico Inflows and Flow at the NIB

Inflow to the Imperial Valley from Mexico and Flow of the Colorado River at the Northerly International Boundary (NIB)

Mexico Inflows and Flow at the NIB

Mexico Inflows vs Colorado R Flow at NIB (1963-99)

Adjustments to Projected Existing Conditions Hydrology

- ◆ **QSA**
- ◆ **Mexico inflows**
- ◆ **Mexico power plants**
- ◆ **Mexico wastewater treatment plant**
- ◆ **Coachella Valley groundwater management**
- ◆ **Entitlement enforcement ?**

Other Adjustments to Mexico Inflows

No Action Inflow Assumptions differ from QSA Documents by including (annual flows averaged over 75 years):

⌘ **Mexicali Power Plants ⇒ - 10,700 AF**

⌘ **Mexicali Wastewater Treatment Plant ⇒ -21,400 AF**

Entitlement Enforcement

◆ Entitlement Enforcement

- ⌘ Currently, 58,856 AF is deducted from projected diversions as a constant
- ⌘ Is there value in matching Entitlement Enforcement reduction to projected diversions rather than using average?
- ⌘ As is....could overestimate the low end and the high end

Current State of Projected Hydrology for No Action

- ◆ table of projected flows by component (revised table 4)

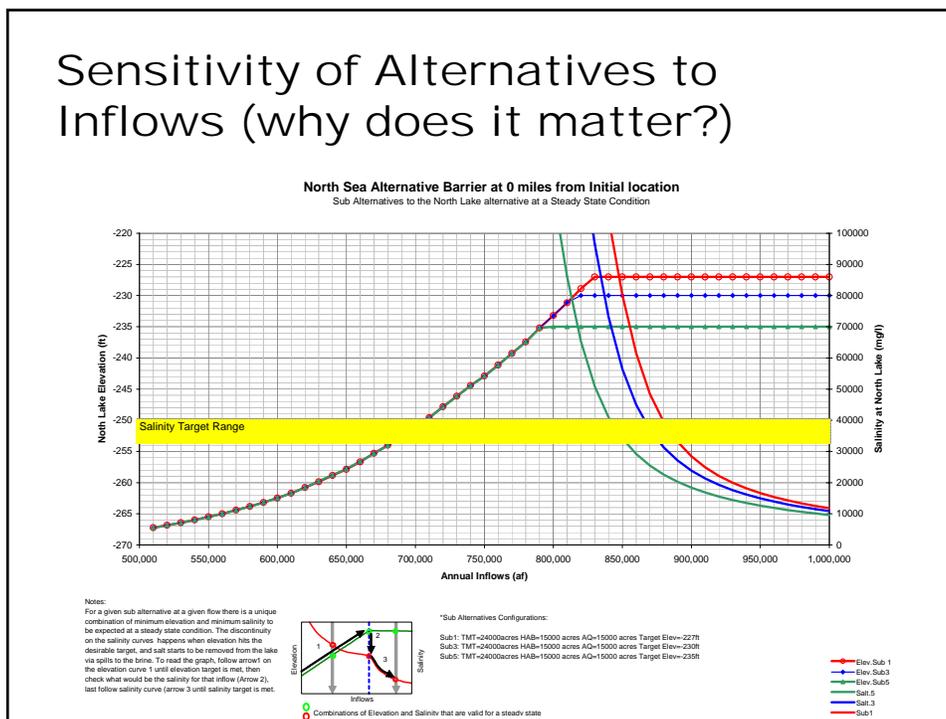

Remaining Items to Complete for No Action

- ◆ **Agree upon approach to Mexico inflows**
- ◆ **Refine calibrated evaporation rates**

Proposed Approach for Addressing Future Uncertainty

- ◆ **Variability and uncertainty**
- ◆ **Why does it matter?**
- ◆ **How will results be used?**
- ◆ **Proposed approach for planning for an uncertain future**
- ◆ **Sources of variability and uncertainty**
- ◆ **Discussion**

Sensitivity of Alternatives to Inflows (why does it matter?)

Use of Results from Uncertainty Analysis

- ◆ **Alternatives to be designed for various inflows**
- ◆ **Range of plausible inflows to be bracketed**
- ◆ **Provide clear, systematic basis for decision making**
- ◆ **Ultimately uncertainty analysis to be used by decision makers to select an alternative**

Proposed Approach

- ◆ **Many sources of future uncertainty**
- ◆ **Uncertainties often dependent on policy-level decisions**
- ◆ **Proposing the use of alternative *Future Hydrologic Scenarios* in addition to No Action hydrology**
 - ⌘ **Similar to what is being proposed in DWR's California Water Plan**
 - ⌘ **"Current Trends", "Less Inflow Limiting", "More Inflow Limiting" scenarios to be used bookends**
 - ⌘ **Other intermediate scenarios may be developed**
- ◆ **Consideration of *factors* that may influence inflows**
- ◆ **Table and discussion**

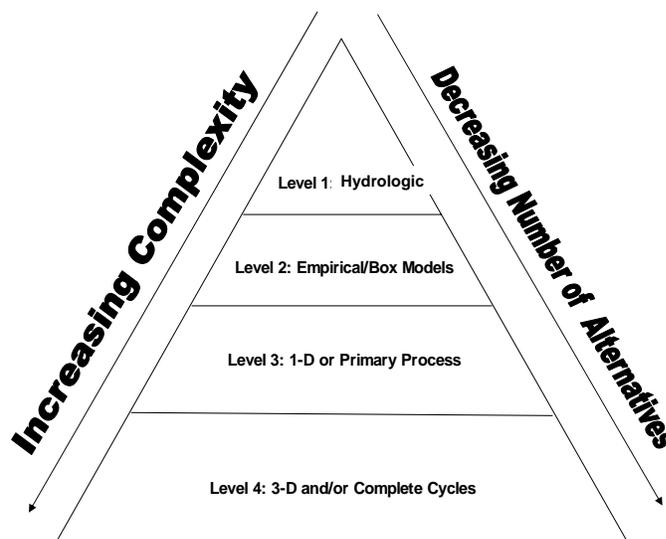

Factors That May Influence Inflow to the Sea

- ◆ **Preliminary list**

Approach to Model Development

- ◆ **Considering a suite of models to account for hydrologic balance, salt balance, water quality, hydraulics, circulation, and other issues**
- ◆ **Hydrologic model first to be developed/applied, others to follow ...**
 - ⌘ **Natural treatment hydraulics and performance**
 - ⌘ **Sea water quality ... nutrient and selenium dynamics**
 - ⌘ **Sea hydrodynamics/circulation**
 - ⌘ **others**

Levels of Analysis and Analytical Approach

Hydrologic Model Requirements

- ◆ **Simulate future Salton Sea elevation and salinity under varying configurations and inflow assumptions**
- ◆ **Account for full water and salt balances**
- ◆ **Monthly and/or annual time steps**
- ◆ **Incorporate multiple impoundments and major components or processes of likely alternatives**
- ◆ **Optimize for simultaneous solution of elevation and salinity targets**
- ◆ **Stochastic simulation capability**
- ◆ **Incorporate evaporation and salt precipitation dynamics as function of salinity**
- ◆ **Publicly-available and documented**
- ◆ **Should include nutrient, selenium approximations? Other processes?**

Proposed Hydrologic Modeling Approach

- ◆ **Develop refined annual inflows and salt loads to represent No Action condition**
- ◆ **Disaggregate annual flows/loads for monthly patterns**
- ◆ **Component-based network of nodes (treatment, habitat, Sea, brine, air quality cells) and arcs (transfer of water/salt between nodes)**
- ◆ **Develop CALSIM-based model for monthly analysis – deterministic version**
- ◆ **Develop stochastic wrapper for uncertainty analysis**

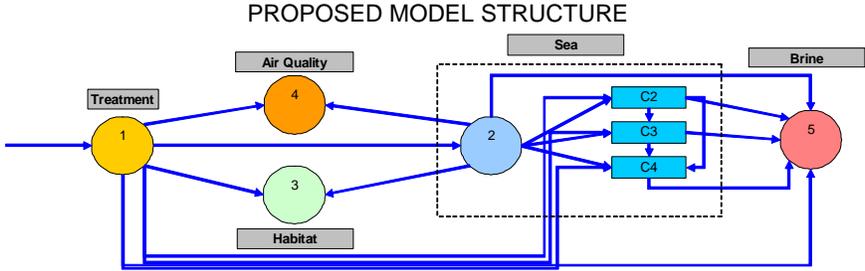

Other Key Modeling and Assumption Issues

- ◆ **Salt loading assumptions**
- ◆ **Salt precipitation dynamics**
- ◆ **Evaporation-salinity relationships**
- ◆ **Consistency in use of climatic data**
- ◆ **Bathymetric survey data**

Proposed CALSIM Hydrologic Model of the Salton Sea

- ◆ **Three basic model elements: wetland, treatment, and sea elements**
- ◆ **Elements serve as approximation for water budgets of:**
 - ⌘ **mechanical treatment system (MTS)**
 - ⌘ **natural treatment system (NTS)**
 - ⌘ **wetland habitat (HAB)**
 - ⌘ **fresh or saline water impoundments (SEA)**
 - ⌘ **air quality mitigation (AQM)**
- ◆ **Alternative configurations are approximated by connectivity of elements**
- ◆ **Water requirements for each are computed based on acreage, salinity, and elevation targets**
- ◆ **Priority weights are assigned to various connections to describe which objectives are to be achieved first**
- ◆ **“Intelligence” of model routes water in most efficient manner given input set of objectives**

Proposed CALSIM Hydrologic Model of the Salton Sea

- ◆ Typical targets to be set will be
 - ⌘ Elevation in one or more of the Sea elements
 - ⌘ Salinity in one or more of the Sea elements
 - ⌘ Blended salinity of delivered water at one or more of the wetland elements
 - ⌘ Preferred flow paths to minimize spills or maximize water use efficiency
